Heterogeneous Parametric Trivariate Fillets

Research Thesis

Submitted in partial fulfillment of the requirements for the degree of Master of Science in Computer Science

Ramy Masalha

Submitted to the Senate of the Technion — Israel Institute of Technology
Nisan 5781 Haifa March 2021
This research was carried out under the supervision of Prof. Gershon Elber, in the Faculty of Computer Science.

Some results in this thesis have been published as articles by the author and research collaborators in conferences and journals during the course of the author’s doctoral research period, the most up-to-date versions of which being:

**Acknowledgements**

First and foremost, I want to thank my supervisor, Gershon Elber, for his continuous, crucial and valuable support through the two years of my research. You exposed me to a new work philosophy of diligence and mastery. You were always more than ready to put the effort of helping me resolve each and every problem, from dealing with the smallest bugs to tackling the most challenging research problems. Your help pushed me toward honing my skills and making the most out of this research.

Secondly, I want to thank my friend and co-author, Emiliano Cirillo, who has put an extraordinary amount of effort into perfecting his part of our paper, even though he had various other commitments and passed through demanding difficult circumstances. Your work is greatly appreciated.

Lastly, I want to thank my parents, Khaled and Fatimah Masalha, for their fully supportive and encouraging attitude. You were there during each stage of my life, and I wish you will always be.

The generous financial help of the Technion is gratefully acknowledged.

Hebrew Abstract i
List of Figures

1.1 This figure shows three blending surfaces (red) built using the cubic Hermite interpolation scheme, for the two surfaces, $S_1(u, v)$ and $S_2(u, v)$. The interpolated rail curves are $C^r_1(u)$ and $C^r_2(u)$. In each picture, a different magnitude of tangent field is used. The red arrows indicate the tangent fields of $\bar{T}_i(u)$. $\bar{T}_i(u)$ denotes normalized and scaled tangent fields, along the rail curves. See also Algorithm 1.

2.1 Euclidean offset curves, $\hat{C}_r_i(t)$, of the intersection curve $C(t)$ of a cylinder $S_1(u, v)$ and a Bézier surface $S_2(u, v)$, on the surfaces $S_1$ and $S_2$.

2.2 A sub-region, $\hat{S}_1(u, v) \in S_1(u, v)$, to be filleted. $\hat{S}_1$ is bounded by the intersection curve, $C(t) = S_1(c^2_2)$, and the rail curve, $C^r_1(t) = S_1(c^r_1)$. (a) shows the preimage of $\hat{S}_1(u, v)$, in the parametric domain of $S_1$, as $s_1$. (b) shows $S_1$ and $\hat{S}_1$ in the Euclidean space, along with a faded version of $S_2$, the second surface to be filleted along intersection curve $C(t)$.

2.3 In (a), the two primary Bézier surfaces, $S_1(u, v)$ and $S_2(u, v)$ are shown, along with the sub-regions of $S_1$ and $S_2$ that are to be filleted, as $\hat{S}_1(u, v)$ and $\hat{S}_2(u, v)$, between the intersection curve, $C(t)$, and the rail curves, $C^r_i \ i \in \{1, 2\}$. $\hat{S}_i(u, v)$ are computed using surface-surface functional composition. Also shown in (a) is the cubic Hermite blending surface, $S_b(u, v)$, between the rail curves. (b) presents the corresponding computed fillet trivariate, $T(u, v, w)$, created by Algorithm 2, as a ruled volume between $\hat{S}_{12} = \hat{S}_1 \cup \hat{S}_2$ and $S_b$.

2.4 In (a), the two primary Bézier surfaces, $S_1(u, v)$ and $S_2(u, v)$ along with their blending surface, $S_b(u, v)$ are shown. In (b), The division of the fillet space into three cube-like topologies is presented in a cross section. Finally, (c) presents the three reconstructed trivariates, $T_i$, in this arrangement, forming together the whole fillet. See also Algorithm 3.

2.5 Auxiliary Figure for Algorithm 3.
2.6 (a) A cylinder, \( S_1(u,v) \), intersects with a sphere, \( S_2(u,v) \). (b) The sphere and the cylinder are subdivided into pairs of matched Bézier sub-surfaces. (c) A fillet trivariate is then created between each pair of Bézier sub-surfaces, as shown in (b). The union of the four fillet trivariates between sub-surfaces form the whole desired fillet of the original cylinder and sphere.

2.7 To create a trivariate volumetric fillet between a planar surface, \( S_j \), and a B-spline cylinder, \( S_i \), the cylinder (and the plane) are subdivided into pairs of matched Bézier patches. In (a), the cylinder, \( S_i(u,v) \), is subdivided along the knot line, \( C_i^{u0}(v) = S_i(u_0,v) \). Then, we find the intersection points, \( I = \{S_j(u_{j0},v_{j0})\} \), between \( C_i^{u0}(v) \) and the intersection curve, \( C(t) \), only to subdivide \( S_j \) at each such intersections, along one of the iso-parametric curves: either \( S_j(u_{j0},v) \) or \( S_j(u,v_{j0}) \). To decide between these two subdivision options, in (b), we compute the unit \( u \)-tangent, \( d_u^j \), and unit \( v \)-tangent, \( d_v^j \), of \( S_j \), at \( S_j(u_{j0},v_{j0}) \), and choose to subdivide along the direction that is the most orthogonal to the unit tangent, \( d_c \), of \( C(t) \), at \( C(t_0) \). Herein, \( S_j \) will be divided along the \( v \) direction.

2.8 During the fillet construction process between the cylinder, \( S_1(u,v) \), and the sphere \( S_2(u,v) \), \( S_2 \) is subdivided along an iso-parametric curve, \( C(v) = S_2(u_0,v) \). If the number of times \( C(v) \) crosses the intersection curve, \( C(t) \), is equal to the number of times \( C(v) \) crosses the rail curve, \( C_2^r(t) \), then the fillet construction continues successfully. Otherwise, the fillet construction fails and is aborted. In (a), the fillet construction fails, because \( C(v) \) crosses \( C_2^r(t) \) twice while it does not cross \( C(t) \). (b) presents (part of) the parametric space of the sphere, \( S_2 \), in (a). In (c) and (d) the cylinder from (a) and (b) is translated a bit so \( C(v) \) crosses both \( C(t) \) and \( C_2^r(t) \) twice, and the fillet construction can be completed successfully.

2.9 In (a), two surfaces, \( S_1(u,v) \) and \( S_2(u,v) \) are shown, along with the subregions of \( S_1 \) and \( S_2 \) that are to be filleted, \( \hat{S}_1 \) and \( \hat{S}_2 \), between the intersection curve, \( C(t) \), and the rail curves, \( C_i^r(t) \). (b) presents (an approximation of) the two subregions, \( \hat{S}_1 \) and \( \hat{S}_2 \), between the intersection curve, \( C(t) \), and the rail curves, \( C_i^r(t) \), computed by the least-square-fitting method described in Section 2.4.3. (c) is a zoom in view of \( \hat{S}_1(u,v) \). (d) presents the computed fillet trivariate, \( T(u,v,w) \), resulting from replacing Line 3 in Algorithm 2 by a least-square-fitting of \( \hat{S}_i \). \( \hat{S}_i \) were sampled at \((12 \times 105)\) locations in the domain, for the least-squares fit, and have \((7 \times 35)\), for \( \hat{S}_1 \), and \((3 \times 35)\), for \( \hat{S}_2 \), control points.
2.10 (a) A cylinder, $S_1$, intersects with a planar surface, $S_2$, along the intersection curve, $C$. $C_i^T$, $i \in \{1, 2\}$, are the rail curves on $S_i$, respectively, and the sub-surface regions, $\hat{S}_i = S_i(Rld(c^S_i, c^T_i))$, are the boundaries of the fillet on $S_i$. (b) presents the half Volumetric Boolean sum trivariate, $T_{\text{hbs}}$, between surfaces, $\hat{S}_1$ and $\hat{S}_2$ (see Definition 2.5.1). Herein, the intersection curve, $C$, is not closed, and hence in (c), two capping surfaces are constructed. $S^\text{Cap}_1$ is computed by trimming the boundary surface $S_1^c$ by curves $C_{S_1}^b(0, v, w)$, $C_{1u}$ and $C_{1v}$. The final V-rep model fillet, created by Algorithm 6, is shown in (d), from a different viewing direction.

2.11 In (a), the spout, $S_1$, of the Utah teapot, is shown intersecting with the body, $S_2$, of the Utah teapot, along the intersection curve, $C$. $C^T_i$, $i \in \{1, 2\}$, are the two rail curves on $S_i$, and the sub-surfaces, $\hat{S}_i = S_i(Rld(c^S_i, c^T_i))$, are the boundaries of the fillet on $S_i$. In (b), the half Volumetric Boolean sum trivariate, $T_{\text{hbs}}$, of $\hat{S}_1$ and $\hat{S}_2$ is presented (see Definition 2.5.1). (c) shows the V-rep model fillet created by Algorithm 6. See also Figure 3.4.

2.12 Filleting over $C^1$ discontinuities. (a) shows all the intersection curves, $C_{i,m,j,m}$, of the cylinder surfaces, $S_{1,i}$, and the surfaces of the box, $S_{2,j}$, as well as the corresponding rail curves. In (b), the Euclidean offset curves from (a) are clipped and stitched together, forming the rail curve(s). Filleting the corresponding pieces, gaps forms at $C^1$ discontinuities, as shown in (c). In (d), the intersection curves, $C_{2,2} = S_{1,2} \cap S_{2,2}$ and $C_{3,0} = S_{1,3} \cap S_{2,0}$, are offseted on the boundary surfaces of the cylinder, $S_{1,2}$ and $S_{1,3}$, forming two disjoint pieces of the rail curve on the cylinder, $R_{2,2}^1$ and $R_{3,0}^1$, that end at $p$ and $q$. A singular fillet is constructed between $p$ and $q$, around $o$, to bridge the gap. Finally, this singular fillet, along with other fillet trivariates form the whole fillet between the box and the cylinder, are shown in (e).

3.1 A heterogeneous fillet computed between two tri-cubic spheres. In (a), the two spheres are shown, after heterogeneous data in $E6$ has been independently encoded into them, as $(x, y, z, r, g, b)$. (b) shows the computed final fillet, following Algorithm 2, while the blending of the $rgb$ properties was computed as described in Section 2.7.1.

3.2 A heterogeneous fillet computed between a sphere and a cone. In (a), intersecting sphere and cone are shown, after heterogeneous data in $E6$ has been independently encoded into both, as $(x, y, z, r, g, b)$. (b) shows the computed fillet, following Algorithm 2, while the blending of the $rgb$ properties was computed as described in Section 2.7.1.
3.3 A heterogeneous fillet computed for the Utah teapot, between the body and the handle. In (a), the regular teapot is shown, after heterogeneous data in $E_6$ has been encoded into, as $(x, y, z, r, g, b)$. (b) shows the computed fillet, following Algorithm 2 while the $rgb$ blending was computed as described in Section 2.7.1. In (c), a 3D printed model is shown, using a Stratasys 3D printer. See also Figure 3.4.

3.4 A heterogeneous fillet computed for the Utah teapot, between the body and the spout. In (a), the regular teapot is shown, after heterogeneous data in $E_6$ has been encoded into, as $(x, y, z, r, g, b)$. (b) shows the computed fillet, following Algorithm 2 while the $rgb$ blending was computed as described in Section 2.7.1. In (c), a 3D printed model is shown, using a Stratasys 3D printer. See also Figure 3.4.
Abstract

Given two objects, blending refers to the creation of a transition surface which smoothly connects boundary surfaces. In this work, we extend the problem of constructing a blending surface to its three-dimensional analog. More specifically, we seek to create a volumetric fillet which smoothly fills the space between two intersecting objects.

Blending and filleting are used for rounding sharp edges or corners, and they are of high importance in the field of computer-aided design. Due to mechanical, aesthetic or other reasons, it is typically desired to replace sharp edges and corners by smooth faces. While methods for constructing a blending surface have been researched intensively in the last decades, to the extent of our knowledge, virtually no research has been conducted on the construction of volumetric fillets.

This work presents several algorithms for the construction of, possibly heterogeneous, trivariate fillets between two, possibly heterogeneous, intersecting trivariates. The input trivariates are assumed to be in $\mathbb{R}^k$, $k \geq 3$, and they can include, in addition to geometric information in $\mathbb{R}^3$, additional (scalar, vector, tensor, etc.) properties, such as material properties. The introduced algorithms operate under different assumptions and support different types of input trivariates.

Our proposed filleting methods either employ functional composition or use the least-square-fitting method to fit a (set of) tensor product trivariate(s) to the boundary surfaces of the input. The result blends between the two inputs, both geometrically and material-wise. The application of encoding heterogeneous material information into the constructed fillet is discussed and examples of all proposed algorithms are presented.
Abbreviations and Notations

$T_1, T_2$: input trivariates, in Euclidean space

$S_1, S_2$: primary surfaces (boundary surfaces of $T_1$ and $T_2$), in Euclidean space

$\mathcal{T}$: the fillet trivariate

$S_b$: blending surface of $S_1$ and $S_2$, in Euclidean space

$C$: intersection curve of $S_1$ and $S_2$, in Euclidean space

$c_i^S$: intersection curve of $S_1$ and $S_2$, in the domain of $S_i$

$c_i^T$: rail curve on $S_i$, in Euclidean space

$c_i^r$: $C_i^r$ in the domain of $S_i$

$T_i$: tangent field of $S_b$, along $C_i^T$

$Rld(c_a, c_b)$: ruled surface between the curves $c_a$ and $c_b$

$Rld(S_a, S_b)$: ruled trivariate between the surfaces $S_a$ and $S_b$

$\hat{S}_i$: the boundary surface of the fillet on $S_i$, in Euclidean space

$\hat{s}_i$: $\hat{S}_i$ in the domain of $S_i$

$\hat{S}_{12}$: the merged surface of $\hat{S}_1$ and $\hat{S}_2$

$C_c$: an interior curve to the fillet space

$C_i$: the projection of $C_c$ on $S_i$, in Euclidean space

$c_i$: the projection of $C_c$ on $S_i$, in the domain of $S_i$

$C_b$: the projection of $C_c$ on $S_b$, in Euclidean space

$c_b$: the projection of $C_c$ on $S_b$, in the domain of $S_b$

$C_i^{u_0}$: $u$ iso-parametric curve of $S_i$ at $u = u_0$

$C_i^{v_0}$: $v$ iso-parametric curve of $S_i$ at $v = v_0$

$\mathcal{T}_{hbs}$: half volumetric Boolean sum trivariate

$\partial \mathcal{T}_k$: boundary surfaces of $\mathcal{T}_k$

$S_{1,i}$: $i$-th boundary surface of $T_1$

$S_{2,i}$: $i$-th boundary surface of $T_2$

$C_{i,j}$: intersection curve of $S_{1,i}$ and $S_{2,j}$, in Euclidean space

$g_i$: property function of $S_i$

$g_{12}$: property function of the merged surface of $S_1$ and $S_2$

$g_b$: property function of $S_b$

$g_T$: property function of $\mathcal{T}$
Chapter 1

Introduction

Given two objects, blending refers to the creation of a transition surface which smoothly connects boundary surfaces. Blending and filleting are used for rounding sharp edges or corners, and they are of high importance in the field of computer-aided design. Due to mechanical, aesthetic or other reasons, it is typically desired to replace sharp edges and corners by smooth faces. The boundary surfaces being connected are called primary surfaces and the boundary curves of the fillet on the primary blending surface are called rail curves (See Figure 1.1). The blending surface is usually required to meet with the primary surfaces with at least $G^1$ continuity. That is, to share a tangent plane with the primary surfaces along the rail curves.

While some use the terms blending and filleting interchangeably, in this thesis, we use blending to refer to the process of constructing a blending surface, and we use filleting to refer to the process of constructing a (set of) trivariate(s) that fill the space between the primary surfaces and their blending surface. The (set of) trivariate(s) that fill this space will be called a fillet.

Consider the two trivariates, $T_1, T_2 \in \mathbb{R}^k, k \geq 3$. $T_i, i \in \{1, 2\}$, can include, in addition to geometric information in $\mathbb{R}^3$, additional (scalar, vector, tensor, etc.) properties for $k > 3$, such as material properties. Let $S_1 \in T_1$ and $S_2 \in T_2$ be two boundary surfaces in $\mathbb{R}^k$ of the trivariates that intersect along curve $C = S_1 \cap S_2$. In this work, we seek to create a volumetric fillet between $S_1$ and $S_2$ along $C$. Here again, $S_1$ and $S_2$ will also be denoted as the primary surfaces. Further, we denote by $c^S_i$ the intersection curve, $C$, in the parametric space of $S_i, i \in \{1, 2\}$. I.e. $C = S_i(c^S_i)$. In the ensuing discussion, small letters will denote geometry in a parametric space, and capital letters will be used to refer to geometry in the Euclidean space. In this work, we assume all parametric forms are sufficiently differentiable (typically at least $C^1$) and regular (their Jacobian never vanish).

In the following section, we briefly outline some preliminary material that is necessary for the next chapters. More details can be found in [CRE01]
1.1 Preliminaries

1.1.1 Parametric Forms

A common approach to represent geometric objects utilizes parametric functions. The number of variables in the parametric function determines the dimension of the geometry. *Univariate* functions are used to define curves, *bivariate* functions are used to define surfaces, and *trivariate* functions are used to define volumes. For example, the following bivariate parametric function describes a unit sphere:

\[ S(\theta, \phi) = (\sin \theta \cos \phi, \sin \theta \sin \phi, \cos \theta), \]
\[ 0 \leq \theta \leq \pi, \; 0 \leq \phi \leq 2\pi. \]

The image of a parametric form is typically in \( \mathbb{R}^k \), where \( k \geq 2 \) for curves and \( k \geq 3 \) for surfaces and trivariates. The first two or three coordinates describe the geometry, while additional coordinates can be possibly used to describe additional (scalar, vector, tensor, etc.) properties, such as material properties.

1.1.2 Tensor Product Parametric Forms

A *tensor product surface*, \( S(u, v) \), is defined as a surface having the following form:

\[ S(u, v) = \sum_{i=0}^{n} \sum_{j=0}^{m} P_{i,j} f_i(u) g_j(v), \]  
\[ (1.1) \]

where \( P_{i,j} \in \mathbb{R}^k \) are called the *control points* of \( S \) and \( f_i, g_j \) are typically (piece-wise) polynomial or rational basis functions. Similarly, a *tensor product trivariate*, \( F(u, v, w) \), is defined as:

\[ F(u, v, w) = \sum_{i=0}^{n} \sum_{j=0}^{m} \sum_{k=0}^{l} P_{i,j,k} f_i(u) g_j(v) h_k(w), \]  
\[ (1.2) \]

For \( P_{i,j,k} \in \mathbb{R}^k \) and typically (piece-wise) polynomial or rational basis functions, \( f_i, g_j \) and \( h_k \). Two common types of basis functions are the Bernstein polynomials and the B-spline basis functions, which are defined in the following sections.

Bézier Functions

The \( i \)-th *Bernstein basis polynomial* of degree \( n \) is defined as:

\[ B_{i,n}(t) = \binom{n}{i} t^i (1-t)^{n-i}. \]  
\[ (1.3) \]

The Bernstein basis polynomials can be substituted in Equation (1.1), resulting with a *Bézier surface* defined in the domain \([0, 1]^2\), and it can be substituted in Equation (1.2), resulting with a *Bézier trivariate* defined in the domain \([0, 1]^3\).
B-spline Functions

Let \( U = u_0 \leq u_1 \leq \ldots \leq u_m \) be a sequence of non-decreasing real numbers. The \( i \)-th B-spline basis function of degree \( n \) over the knot vector \( U \), where \( 0 \leq i \leq m - n + 1 \), is defined as follows.

\[
N_{i,0}(u) = \begin{cases} 
1 & \text{if } u_i \leq u < u_{i+1}, \\
0 & \text{otherwise}, 
\end{cases}
\]

and for degree \( n > 0 \),

\[
B_{i,n}(u) = \begin{cases} 
\frac{u - u_i}{u_i + n - u_i} N_{i,n-1}(u) + \frac{u_{i+n+1} - u}{u_{i+n+1} - u_{i+1}} N_{i+1,n-1}(u) & \text{if } u_i \leq u < u_{i+n+1}, \\
0 & \text{otherwise}. 
\end{cases}
\]

(1.4)

The B-spline basis functions can be substituted in Equations (1.1) and (1.2), resulting with a B-spline surface and a B-spline trivariate (respectively). Existing algorithms support subdividing a B-spline surface into several Bézier patches, and this work will make use of such algorithms. Refer to [CRE01] for more on this B-spline subdivision process.

The rest of this document is organized as follows. In Chapter 2, we present several algorithms toward heterogeneous fillet construction, that support varying sets of parametric surface types, and operate under different assumptions. Then, in Chapter 3, we present results and examples of the described algorithms. Finally, we conclude in Chapter 4.
Figure 1.1: This figure shows three blending surfaces (red) built using the cubic Hermite interpolation scheme, for the two surfaces, $S_1(u, v)$ and $S_2(u, v)$. The interpolated rail curves are $C_1^r(u)$ and $C_2^r(u)$. In each picture, a different magnitude of tangent field is used. The red arrows indicate the tangent fields of $\bar{T}_i(u)$. $\bar{T}_i(u)$ denotes normalized and scaled tangent fields, along the rail curves. See also Algorithm 1.
Chapter 2

Heterogeneous Fillet Construction Algorithms

In this chapter, we discuss several approaches to construct a (set of) trivariate fillet(s) between the two input trivariates. Because the algorithms we introduce only make use of the boundary surfaces of the input trivariates (possibly with their heterogeneous properties, in \( \mathbb{R}^k, k \geq 3 \)), hence after, we will consider the input to be \( S_1 \) and \( S_2 \), rather than \( T_1 \) and \( T_2 \). The following section reviews background material and introduce functionalities that will be exploited in the proposed filleting algorithms.

2.1 Background and Used Functionalities

2.1.1 Cubic Hermite Blending Surface

A common approach to construct a blending surface uses the cubic Hermite interpolation scheme [CRE01], which offers a \( C^1 \) continuity. Given two rail curves, \( C^1_r(u) \) and \( C^2_r(u) \), and two tangent fields along them, \( T_1(u) \) and \( T_2(u) \), the following surface interpolates the given rail curves and reconstructs the given tangent fields along them:

\[
S_b(u, v) = C^1_r(u)h_{00}(v) + C^2_r(u)h_{01}(v) + T_1(u)h_{10}(v) + T_2(u)h_{11}(v),
\]

where \( h_{ij}(v) \) are the cubic Hermite basis functions. Figure 1.1 shows three examples of a cubic Hermite blending surface with different magnitudes of tangent fields, \( T_i \), along the boundaries, while the rail curves and the directions of the tangent fields are all kept the same. This blending scheme will be extended and employed here, toward heterogeneous trivariate fillets.

2.1.2 Constructing the Rail Curves

While the rail curves (and their associated tangent fields) can also be provided by the end user, herein we offer an additional way to construct them. Let \( S_1 \) and \( S_2 \) be the two
given surfaces, and let $C$ be their intersection curve. The default construction scheme we offer to use as rail curves is using a Euclidean offset approximation of $C$, lying on $S_1$ and $S_2$. More precisely, let $C^r_i$ be a curve on $S_i$ located at Euclidean distance $d$ from $C$, the intersection curve. Then, $C^r_i$, which is denoted the Euclidean offset curve of $C$ on $S_i$, can be used as a rail curve in the construction of the blending surface. Figure 2.1 shows an example of two resulting Euclidean offset rail curves, when the primary surfaces are a cylinder and a general Bézier surface. See [EK20] for more on this Euclidean offset-approximation computation on surfaces. In the rest of this work, we assume the rail curves, $c^r_i$, are provided.

2.1.3 Constructing the Tangent Fields

The tangent fields are necessary to ensure $G^1$ continuity. Given the rail curves, we seek univariate tangent fields, along the rail curves, in the tangent fields of the primary
surfaces, that are also orthogonal to the direction of the rail curves. These tangent fields are hence computed, for a rail curve \( C_i^r(t) = S_i(c_i^r(t)) \), as

\[
T_i(t) = C_i^r(t) \times (N_i(c_i^r(t)))
\]

where \( N_i(u,v) \) is the normal field of \( S_i = S_i(u,v) \) as \( N_i = \frac{\partial S_i}{\partial u} \times \frac{\partial S_i}{\partial v} \).

At each point, the resulting tangent field is simultaneously orthogonal to the normal of \( S_i \) (which means it lies in the corresponding tangent plane), and to the tangent field of \( C_i^r \), \( C_i'^r \). Note we assume regularity of \( C_i^r \) and \( S_i \), and hence \( T_i \) is well defined.

We also seek to give the user control over the magnitude of the tangent fields. Hence, we approximate the normalized tangent fields, only to scale these fields by a user-specified parameter. Because normalization of a rational field is typically not rational, the normalization of the tangent field, is approximated, following [KE97]. Again, Figure 1.1 shows three examples of a blending surface with different magnitudes of tangent fields along the given rail curves, and where \( T \) denotes the normalized fields.

### 2.1.4 Constructing a Blending Surface

In summary, we construct a blending surface using the cubic Hermite interpolation scheme, with two positional constraints (the rail curves), as explained in Section 2.1.2, and two tangential constraints, as explained in Section 2.1.3. Algorithm 1 summarizes the process of creating a blending surface.

**Algorithm 1**: Computing a blending surface.

**Input:**
- \( S_1(u_1,v_1), S_2(u_2,v_2) \) - primary surfaces;
- \( c_i^r(t) \) - rail curve in the parameter space of \( S_i \);
- \( \tau \) - control over the magnitudes of the tangents;

**Output:**
- \( B \) - a cubic Hermite blending surface;

1. \( \text{BlendingSrf}(S_1, S_2, c_1^r, c_2^r, \tau) \):
2. \hspace{1em} \text{for } j \leftarrow 1 \text{ to } 2 \text{ do}
3. \hspace{2em} C_i^r(t) = S_i(c_i^r(t));
4. \hspace{2em} N_i(u, v) = \frac{\partial S_i(u,v)}{\partial u} \times \frac{\partial S_i(u,v)}{\partial v};
5. \hspace{2em} T_i(t) = C_i'^r(t) \times N_i(c_i^r(t));
6. \hspace{2em} \hat{T}_i(t) = \frac{T_i(t)}{||T_i(t)||}; \hspace{1em} \text{// An approximation}
7. \hspace{2em} S_b(u,v) = C_1^r(u)h_{00}(v) + C_2^r(u)h_{01}(v) + \tau \hat{T}_1(u)h_{10}(v) + \tau \hat{T}_2(u)h_{11}(v);
8. \hspace{1em} \text{return } B;

### 2.1.5 Surface-Surface Functional Composition

We have already seen in this work use-cases of curve-surface functional composition. For example, when the normal field of \( S_i \) was restricted to the univariate rail curve
c_i(t), as N_i(c_i(t)). However, the computation of surface-surface composition places some additional challenges that must be discussed.

Unlike the cases of blends of surfaces, here, for volumetric, trivariate, fillets, we will also be required to represent general, non iso-parametric, sub-region of the primary surfaces. Specifically, we seek to precisely represent and interpolate the surface sub-region of S_i between the intersection curve and the rail curve. We seek a tensor product representation for this sub-region, Ĥ_i(s, t) ⊂ S_i(u, v), in order to employ it in the trivariate fillet construction. Toward this end, we will mostly exploit surface-surface composition [Elb92, DGHM93], as follows:

\[ \hat{S}_i(s, t) = S_i(Rld(c_i(t), c_S^i(t))), \]  

(2.2)

where \( Rld(\cdot, \cdot) \) denotes a ruled surface between the two given parametric curves:

\[ Rld(c_i(t), c_S^i(t)) = (1 - v)c_i(t) + vc_S^i(t), v \in [0, 1]. \]  

(2.3)

See Figure 2.2. Note \( S_i \) and hence \( \hat{S}_i \) can reside in \( \mathbb{R}^k, k \geq 3 \) and contain geometric prescriptions but also additional (material) properties.

A difficulty arises in obtaining a representation of the required sub-regions by functional composition when a sub-region of surface \( \hat{s}_i \) that participate in the fillet crosses a knot line in the domain of \( S_i \), an arrangement we denote B-spline surfaces in general position. The composition, \( S_i(\hat{s}_i) \), of a tensor product spline function \( S_i \) with another spline function \( \hat{s}_i \) is no longer a tensor product spline if \( \hat{s}_i \) crosses a knot line in the domain of \( S_i \), in a general (non iso-parametric) way. Hence, and after discussing previous work in Section 2.2, in Section 2.3, we assume that the primary surfaces are polynomial/Bézier (as it is clear that the composition of two polynomial surfaces is yet another polynomial surface) and construct fillets consisting of tensor product trivariates. Then, we will (partially) deal with the difficulty of crossing knot lines, in several ways, in Section 2.4. In Section 2.5, the exploitation of trimmed trivariates in building volumetric fillets is discussed, as an alternative, and in Section 2.6, we deal with the problem of filleting over trivariates with \( C^1 \) discontinuities. Finally, in Section 2.7, an approach to blend and encode property values, in \( \mathbb{R}^k \), into the fillet, is considered.

2.2 Related Work

Methods for constructing blending surfaces have been researched intensively in the last decades, and we sample this rich body. [BI92] and [GL02] utilize the Hermite interpolation scheme to construct blending surfaces, and [SKJ90] constructs a mathematical model for a blending surface generated by rolling a ball between the two primary surfaces. [VMV89] discusses methods to solve topological problems, such as vertex crossing, that may be faced when constructing a blending surface and [LXL14, Che03] represent
a blending surface as a set of curves. See [VMV94] for a survey of blending techniques.

Several algebraic methods have been proposed to construct blending surfaces. These algebraic methods include, for example, solving a set of ordinary differential equations (ODEs) or partial differential equations (PDEs), as in [YTT18, YUT+14], solving an optimization problem, as in [FPS19], and utilizing Grobner basis methods, as in [rWsZ00].

The blending surface is typically required to meet with the primary surfaces with $G^1$ continuity, but some works construct a blending surface that satisfies further requirements or have different features. [BZ09] provides a method for constructing a blending surface which is $G^n$ continuous to the primary surfaces, [YTT18] deals with the construction of blending surface with curvature continuity, [FPS19] requires the constructed blending surface to optimize different measures, such as maximal deviation and uniformity of parametric speed, and [Elb05] proposes a method for the construction of shaped blending surfaces for decoration purposes.

The problem of constructing a blending surface has been tackled within various contexts. [ZWH12, BLK17, CT03] deal with constructing a blending surface between multiple surfaces. [Li04, Hsu06] discuss methods for the blending of implicit surfaces. [YTW19] deals with the blending of time-dependent parametric surfaces and [HH88] discusses the problem of blending two surfaces in projective space.

All the above work has focused on blending surfaces, and to the extent of our knowledge, no research has been conducted on the construction of trivariate fillets. In this work, we propose several algorithms toward this end, of constructing volumetric trivariate fillets.

We are also interested in previous work on the blending and encodement of heterogeneous property functions. [BST04], for example, propose several distance-based methods for the purpose of material blending, such as convex combination of the materials at different regions, and [SK04]; and [SK05] introduce methods for the blending of material represented by free-form functions and solve an optimization problem to determine material variation. More recently, [AW19] dealt with the encoding of properties into transition regions by associating each transition region with a transition function, and setting the property value at a given point in a specific transition region to a combination of several transition functions. Additionally, [CE20] tackled the encodement of properties over V-rep models by a feature preserving blending scheme.

Some other works offer methods to support Boolean operations on heterogeneous objects. [KD98] represent heterogeneous material by $r_m$-objects, which are collections of $r_m$-sets, and define Boolean operations over them. [DS01, Shi02] propose material blending approaches of two heterogeneous primitive sets involved in a Boolean operation, based on a convex combination of the two materials, and [KTS06] utilize non-manifold cellular representation and heterogeneous features tree representation to model complex heterogeneous objects. Finally, see [KT07, LFF+20] for extensive reviews of the literature on heterogeneous object modeling.
Figure 2.2: A sub-region, $\hat{S}_1(u, v) \in S_1(u, v)$, to be filleted. $\hat{S}_1$ is bounded by the intersection curve, $C(t) = S_1(c(t))$, and the rail curve, $C_1(t) = S_1(c_1(t))$. (a) shows the preimage of $\hat{S}_1(u, v)$, in the parametric domain of $S_1$, as $s_1$. (b) shows $S_1$ and $\hat{S}_1$ in the Euclidean space, along with a faded version of $S_2$, the second surface to be filleted along intersection curve $C(t)$.

Compared to previous works, this work extents the thoroughly investigated problem of the construction of blending surface to the volumetric context of trivariate filleting, and discusses the application of heterogeneity encodement methods over the constructed fillets. The filleting algorithms we introduce support varying sets of parametric surface types, and operate under different assumptions, while the resulting fillets (smoothly) blend the two inputs, both geometrically and material-wise. The practicality of our methods is demonstrated by various examples, such as 3D printing of the constructed heterogeneous fillet, in Chapter 3.

2.3 Trivariate Fillet Construction between Two Bézier Surfaces

Following the difficulties in performing the required surface-surface composition operations, as portrayed in Section 2.1.5, in this section, we assume the input primary surfaces, $S_1$ and $S_2$, are polynomial Béziers. Recall we denoted by $Rld(\cdot, \cdot)$ the ruled surface between two curves. Similarly, for any two surfaces $S_a(u, v)$ and $S_b(u, v)$ defined over $[0, 1]^2$, we denote by $Rld(S_a, S_b)$ the ruled volume between $S_a$ and $S_b$:

$$Rld(S_a, S_b)(u, v, w) = (1 - w)S_a(u, v) + wS_b(u, v), w \in [0, 1]. \quad (2.4)$$

The following sections introduce our first trivariate fillet construction algorithms between two, possibly heterogeneous, Bézier boundary surfaces.
2.3.1 Constructing a Trivariate Fillet by a Ruled Volume

Given $\hat{S}_1(u, v)$, $u, v \in [0, 1]$, $i \in \{1, 2\}$, as in Equation (2.2), denote by $\hat{S}_{12} = \hat{S}_1 \cup \hat{S}_2$ the merged along $C$ surface:

$$
\hat{S}_{12} = \hat{S}_1 \cup \hat{S}_2 = \begin{cases}
\hat{S}_1(u, 2v), & 0 \leq v \leq 0.5, \\
\hat{S}_2(u, 2(v - 0.5)), & 0.5 < v \leq 1.
\end{cases}
$$

(2.5)

The fillet we aim to create is bounded in between $\hat{S}_{12}$ and the blended surface, $S_b(u, v)$, as in Equation (2.1) and Algorithm 1. Hence, a ruled volume between $\hat{S}_{12}$ and the blended surface can serve as the desired fillet:

$$
\mathcal{T}(u, v, w) = Rld(\hat{S}_{12}(u, v), S_b(u, v)),
$$

after matching the domain and the functional spaces of $S_{12}$ and $S_b$, via degree raising and refinements.

Note both $\hat{S}_{12}(u, v)$ and $S_b(u, v)$ and hence $\mathcal{T}(u, v, w)$ can reside in $\mathbb{R}^k$, $k \geq 3$ and may contain geometric prescriptions but also additional properties. Algorithm 2 summarizes the process of constructing a fillet trivariate using this formulation, as a ruled volume. Figure 2.3 shows a resulting trivariate fillet of using Algorithm 2, over two Bézier surfaces.

2.3.2 Constructing a Trivariate Fillet by a Volumetric Boolean Sum

The fillet construction scheme presented in Section 2.3.1 has two complete surface faces of the fillet trivariate vanishing into curves, along the rail curves. Such singularities must be difficult in some applications and hence herein, we consider an alternative.

We utilize the volumetric Boolean sum operation [EKK12], which computes a tensor...
product trivariate representation of a space enclosed by six surfaces sharing boundaries in a cube-like topology. However, the desired fillet space, enclosed by $S_1$, $S_2$ and $S_b$, does not present a cube topology. Hence, the fillet construction algorithm introduced in this section, starts by subdividing the fillet space into three sub-spaces, each having a cube-like topology (see Figure 2.4).

The division method goes as follows. Let $C_c(t)$ be a curve in the interior of the fillet space, and let $C_1(t)$, $C_2(t)$ and $C_b(t)$ be three curves on $S_1(u,v)$, $S_2(u,v)$ and $S_b(u,v)$, respectively. The three ruled surfaces, $Rld(C_c, C_1)$, $Rld(C_c, C_2)$ and $Rld(C_c, C_b)$, divide the fillet space into three sub-spaces having each a cube topology, and the volumetric Boolean sum operation is employed to construct a separate fillet trivariate for each sub-space.

While almost any curve, $C_c(t)$, inside the fillet space, and almost any three curves $C_1(t) \subseteq S_1(u,v)$, $C_2(t) \subseteq S_2(u,v)$ and $C_b(t) \subseteq S_b(u,v)$, are suitable to perform the above division process, we seek to choose curves that will (approximately) satisfy the following two requirements:

1. For symmetry purposes, the curve $C_c$ is desired to be (approximately) equidistant from the three surfaces $S_1$, $S_2$ and $S_b$.

2. Aiming at stable Jacobian values in all three trivariates, we strive for the three constructed fillet trivariates to be (approximately) equiangular, near $C_c(t)$.

A details one possible approach to the computation of this arrangement while an accurate computation of the curve $C_c$, so it is precisely equidistant from $S_1$, $S_2$ and $S_b$, can be sought by defining $C_c$ to be the trisector of the three surfaces $S_1$, $S_2$ and $S_b$.

---

**Algorithm 2:** computing a filleting trivariate by a ruled volume, for Bézier primary surfaces.

**Input:**
- $S_1(u_1,v_1)$, $S_2(u_2,v_2)$ - the primary Bézier surfaces;
- $c^r(t)$ - rail curve in the parameter space of $S_1$;
- $c^S_1(t)$ - intersection curve in the parameter space of $S_1$;
- $C(t)$ - intersection curve in Euclidean space;
- $\tau$ - control over the magnitudes of the tangents;

**Output:**
$T$, a filleting trivariate;

1. **BzrTrivarFillet**($S_1$, $S_2$, $c^r_1$, $c^r_2$, $c^S_1$, $c^S_2$, $C$, $\tau$):
   2. for $i \leftarrow 1$ to 2 do
   3. \[ \hat{S}(u,v) = S_i(Rld(c^S_i, c^r_i)); \] // Figure 2.2
   4. $\hat{S}_{12}(u,v) = \hat{S}_1 \cup \hat{S}_2$; // Equation (2.5)
   5. $S_b(u,v) = BlendingSrf(\hat{S}_1, \hat{S}_2, c^r_1, c^r_2, \tau)$; // Algorithm 1
   6. $T(u,v,w) = Rld(\hat{S}_{12}(u,v), S_b(u,v))$; // Ruled volume between matched domains/function spaces
   7. return $T$;

---
and letting $C_1$, $C_2$ and $C_b$ be the foot supporting curves of trisector $C_c$ on $\hat{S}_1$, $\hat{S}_2$, and $\hat{S}_b$, respectively. The trisector of three surfaces can be computed via six constraints with seven unknowns, as shown in [BEH10]. However, herein, and for simplicity of the computation, we follow the approximation approach explained in A.

Then, and having these supporting curves, the three trivariates are constructed following Algorithm 3, that together form the whole fillet. See also the cross section sketch of the associated surface in Algorithm 3, that are used in each of the three trivariates. Note that while the volumetric Boolean sum operation is typically executed over six boundary surfaces forming a cube topology, Algorithm 3 employs the volumetric Boolean sum over only four surfaces forming a sleeve. Two capping surfaces are automatically generated from the four provided surfaces, from the two open ends of the sleeve - Two sets of four boundary curves of the four provided surfaces. In this work, the generation of the capping surfaces has been done using the Boolean sum method [CRE01]. Figure 2.4 (c) shows one result of executing Algorithm 3 on two primary Bézier surfaces.
Algorithm 3: Computing filleting trivariates via volumetric Boolean sum operations.

Input:
$S_1(u_1, v_1), S_2(u_2, v_2)$ - the primary Bézier surfaces;
$c_r^i(t)$ - rail curve in the parametric space of $S_i$;
$C_c$ - the interior curve to the fillet space;
$C_i = S_i(c_i)$ - The projection curve of $C_c$ on $S_i i \in \{1, 2\}$;
$C_b = S_b(c_b)$ - The projection curve of $C_c$ on $S_b$;
$c_T^i(t)$ - Intersection curve in the parametric space of $S_i$;

Output:
$T_1, T_2$ and $T_3$ - Three trivariates forming the whole fillet:

1. $\text{BzrTrivFilletBoolSum}(S_1, S_2, c_1^1, c_2^1, C_1, C_2, C_b, c_T^1(S_1), c_T^2(S_2))$:

   \[
   T_1(u, v, w) = VBS(\text{ // Volumetric Boolean sum})
   \]
   \[
   S_1(Rld(c_T^1, c_1)), \text{ // Fig. 2.5, curve 1}
   \]
   \[
   Rld(C_1, C_c), \text{ // Fig. 2.5, curve 2}
   \]
   \[
   Rld(C_c, C_2), \text{ // Fig. 2.5, curve 3}
   \]
   \[
   S_2(Rld(c_T^2, c_2)); \text{ // Fig. 2.5, curve 4}
   \]

2. $\text{T}_2(u, v, w) = VBS(\text{ // Volumetric Boolean sum})$

   \[
   S_1(Rld(c_1^1, c_1)), \text{ // Fig. 2.5, curve 5}
   \]
   \[
   S_b(Rld(c_T^1, c_b)), \text{ // Fig. 2.5, curve 6}
   \]
   \[
   Rld(C_b, C_c), \text{ // Fig. 2.5, curve 7}
   \]
   \[
   Rld(C_c, C_1); \text{ // Fig. 2.5, curve 2}
   \]

3. $\text{T}_3(u, v, w) = VBS(\text{ // Volumetric Boolean sum})$

   \[
   S_b(Rld(c_b, c_2^2)), \text{ // Fig 2.5, curve 8}
   \]
   \[
   S_2(Rld(c_2^2, c_2)), \text{ // Fig 2.5, curve 9}
   \]
   \[
   Rld(C_2, C_c), \text{ // Fig 2.5, curve 3}
   \]
   \[
   Rld(C_c, C_b); \text{ // Fig 2.5, curve 7}
   \]

return $\{T_1, T_2, T_3\}$;

Figure 2.5: Auxiliary Figure for Algorithm 3
2.4 Trivariate Fillet Construction between Two B-spline Surfaces

The filleting Algorithms introduced in the previous sections assume the two primary surfaces, \( S_1 \) and \( S_2 \), are Bézier surfaces. In this section, we discuss how it is possible to extend these algorithms to support B-spline based geometry under certain assumptions (that are explained in Section 2.4.2). The algorithms described in this section divide the input B-spline surfaces, \( S_1 \) and \( S_2 \), into pairs of Bézier sub-surfaces. Then, for each such pair of Bézier surfaces, we compute their trivariate fillet, so that their union provides the whole fillet of the input B-spline geometry (see Figure 2.6). Section 2.4.1 describes how the subdivision locations of \( S_1 \) and \( S_2 \) are computed, and Section 2.4.2 introduces the subdivision and fillet construction algorithm, and explains the assumptions we make on \( S_1 \) and \( S_2 \) to ensure that the algorithm can be applied. As not all cases of volumetric fillets for input tensor product B-spline geometry can be reduced to a fillet trivariate between a set of tensor product Bézier pairs, in Section 2.4.3, an alternative to the fillet construction that circumvents the surface-surface composition altogether is considered, at the cost of being only an approximation.

2.4.1 Computing the Subdivision locations in the B-spline surfaces

The values along which \( S_1 \) and \( S_2 \) will be subdivided are computed as follows. As a first step, \( S_1 \) and \( S_2 \) are subdivided along all of their interior knots, leaving only Bézier patches. Let \( S_i \) be one of the input surfaces \( \{ S_1, S_2 \} \) and let \( S_j \) be the other surface. For each \( u \)-knot, \( u_{i0} \), and each \( v \)-knot, \( v_{i0} \), of \( S_i \), let \( C_{i0}^{u}(v) = S_i(u_{i0}, v) \) and \( C_{i0}^{v}(u) = S_i(u, v_{i0}) \) be the corresponding iso-parametric curves of \( S_i \). Now consider the intersection locations, \( I \), of \( S_j \) and curves \( C_{i0}^{u}(v) \) or \( C_{i0}^{v}(u) \), if any. \( S_j \) will be further subdivided at all \( I \), in either \( u \) or \( v \). We now describe how to compute the subdivision values of \( S_j \) corresponding to the set \( I \) for \( S_j \cap C_{i0}^{u} \), while the subdivision values corresponding to the set of intersection points \( S_j \cap C_{i0}^{v} \) are similarly computed. See Figure 2.7.
Figure 2.7: To create a trivariate volumetric fillet between a planar surface, \( S_j \), and a B-spline cylinder, \( S_i \), the cylinder (and the plane) are subdivided into pairs of matched Bézier patches. In (a), the cylinder, \( S_i(u, v) \), is subdivided along the knot line, \( C_i^{u_0}(v) = S_i(u_0, v) \). Then, we find the intersection points, \( \mathcal{I} = \{ S_j(u_{j0}, v_{j0}) \} \), between \( C_i^{u_0}(v) \) and the intersection curve, \( C(t) \), only to subdivide \( S_j \) at each such intersections, along one of the iso-parametric curves: either \( S_j(u_{j0}, v) \) or \( S_j(u, v_{j0}) \). To decide between these two subdivision options, in (b), we compute the unit \( u \)-tangent, \( d_j^u \), and unit \( v \)-tangent, \( d_j^v \), of \( S_j \), at \( S_j(u_{j0}, v_{j0}) \), and choose to subdivide along the direction that is the most orthogonal to the unit tangent, \( d_c \), of \( C(t) \), at \( C(t_0) \). Herein, \( S_j \) will be divided along the \( v \) direction.

Let \( c_i^{S_j}(t) = (u^{S_i}(t), v^{S_i}(t)) \) be the intersection curve in \( S_i \)'s parametric space and let \( C(t) = S_j(u^{S_j}(t), v^{S_j}(t)) \) be its Euclidean image. Given \( u \)-knot \( u_{i0} \), using a univariate solver (e. g. [ME18]), we solve the following constraint in \( t \):

\[
u^{S_i}(t) = u_{i0}, \quad (2.6)
\]

to find all the value(s), \( \{t_0\} \), for which the \( u \)-coordinate of the intersection curve, \( c_i^{S_j}(t_0) \), is equal to \( u_{i0} \). Note that \( t_0 \) is a solution of Equation (2.6) if and only if the intersection curve, \( C(t) = S_i(u^{S_i}(t), v^{S_i}(t)) \), intersects with the iso-parametric curve, \( C_i^{u_0}(v) = S_i(u_{i0}, v) \), at the point \( C(t_0) \). That is, \( C_i^{u_0} \) intersects with the other surface, \( S_j \), at \( C(t_0) \). For each such \( t_0 \), let \( (u_{j0}, v_{j0}) = c_i^{S_j}(t_0) \) be the intersection point in \( S_j \)'s parametric space.

Having an intersection point identified, we either subdivide \( S_j \) at the \( u \)-value, \( u_{j0} \), or at the \( v \)-value, \( v_{j0} \). Ideally, we aim to subdivide \( S_j \) in a direction orthogonal to the intersection curve, at the intersection point \( C(t_0) \), because such orthogonality would make the fillet more fair-looking and the computation more numerically stable (better Jacobians). Let \( d_j^u \) and \( d_j^v \) be the unit \( u \)-tangent and unit \( v \)-tangent of \( S_j \) at the point \( (u_{j0}, v_{j0}) \) (see Figure 2.7(b)), respectively, and let \( d_c \) be the unit tangent of the intersection curve, \( C \), at \( C(t_0) = S(u_{j0}, v_{j0}) \). If \( |\langle d_j^u, d_c \rangle| < |\langle d_j^v, d_c \rangle| \), the \( u \)-value, \( u_{j0} \), is added to the subdivision values of \( S_j \). Otherwise, the \( v \)-value, \( v_{j0} \), is added.

Algorithm 4 summarizes the computation process of these subdivision values.

### 2.4.2 The Fillet Construction

Recall that the fillet we seek to create is bounded by sub-regions \( \hat{S}_i = S_i(R_{ld}(c_i^{S_i}, c_i^T)) \) (recall Figure 2.2). The subdivision of \( S_1 \) and \( S_2 \) along the parametric values computed
**Algorithm 4:** Computing subdivision values for B-spline primary surfaces.

**Input:**
- $S_1(u_1, v_1)$, $S_2(u_2, v_2)$ - B-spline primary surfaces;
- $C$ - intersection curve in Euclidean space;
- $c^{S_1}_I$ - intersection curve in the parametric space of $S_1$;
- $c^{S_2}_I$ - intersection curve in the parametric space of $S_2$;

**Output:**
- $L^u_i$ - subdivision values of $S_i$ in the $u$ parameter direction;
- $L^v_i$ - subdivision values of $S_i$ in the $v$ parameter direction;

**GetSubdivVal**($S_1, S_2, C$):

1. $L^u_1$, $L^v_1$ = interior knots of $S_1$ in $u$ and $v$;
2. $L^u_2$, $L^v_2$ = interior knots of $S_2$ in $u$ and $v$;
3. for $i$ ← 1 to 2 do
   - $j = (i == 1)? 2 : 1$
   - foreach $u$-knot, $u_{i0}$, of $S_i$ do
     - $C^u_{i0}(v) = S_i(u_{i0}, v)$;
     - foreach $C(t_0) \in C^u_{i0} \cap C$ do
       - AddSubdivVal($S_j, c^{S_j}_I, t_0, L^u_j, L^v_j$);
   - foreach $v$-knot, $v_{i0}$, of $S_i$ do
     - $C^v_{i0}(u) = S_i(u, v_{i0})$;
     - foreach $C(t_0) \in C^v_{i0} \cap C$ do
       - AddSubdivVal($S_j, c^{S_j}_I, t_0, L^u_j, L^v_j$);
4. return $L^u_1, L^v_1, L^u_2, L^v_2$;

// Auxiliary function

**Function** AddSubdivVal($S, c, t_0, L^u, L^v$):

1. $(u, v) = c(t_0)$;
2. $C = S(c)$;
3. $d_u = \frac{\partial S(u, v)}{\partial u} / \| \frac{\partial S(u, v)}{\partial u} \|$
4. $d_v = \frac{\partial S(u, v)}{\partial v} / \| \frac{\partial S(u, v)}{\partial v} \|$
5. $d_c = \frac{dC(t)}{dt} / \| \frac{dC(t)}{dt} \|$
6. if $|\langle d^u_j, d_c \rangle| < |\langle d^v_j, d_c \rangle|$ then
    - $L^u = L^u \cup \{u\}$;
8. else
    - $L^v = L^v \cup \{v\}$;
Figure 2.8: During the fillet construction process between the cylinder, \( S_1(u, v) \), and the sphere \( S_2(u, v) \), \( S_2 \) is subdivided along an iso-parametric curve, \( C(v) = S_2(u_0, v) \). If the number of times \( C(v) \) crosses the intersection curve, \( C(t) \), is equal to the number of times \( C(v) \) crosses the rail curve, \( C_2^r(t) \), then the fillet construction continues successfully. Otherwise, the fillet construction fails and is aborted. In (a), the fillet construction fails, because \( C(v) \) crosses \( C_2^r(t) \) twice while it does not cross \( C(t) \). (b) presents (part of) the parametric space of the sphere, \( S_2 \), in (a). In (c) and (d) the cylinder from (a) and (b) is translated a bit so \( C(v) \) crosses both \( C(t) \) and \( C_2^r(t) \) twice, and the fillet construction can be completed successfully.

by Algorithm 4, also imposes a similar subdivision on \( \hat{S}_1 \) and \( \hat{S}_2 \), the sub-regions between the rail curves and the intersection curve. The subdivided patches of \( \hat{S}_1 \) and \( \hat{S}_2 \) will be denoted \( \hat{S}_{1,1}, \ldots, \hat{S}_{1,m} \) and \( \hat{S}_{2,1}, \ldots, \hat{S}_{2,m} \), respectively. The fillet construction algorithm we introduce in this section operates under the assumption that \( n = m \), and it constructs a separate trivariate fillet between each \((\hat{S}_{1,i}, \hat{S}_{2,i})\) pair. However, in general, we don’t have a tensor product representation of \( \hat{S}_1 \) and \( \hat{S}_2 \), to ensure that \( n = m \) so that \( \{\hat{S}_{1,i}\} \) and \( \{\hat{S}_{2,i}\} \) can be properly matched. Hence, the following condition is verified: on each subdivision step, and for each iso-parametric curve, \( C \), corresponding to one of \( S_i \)’s subdivision values \((i \in \{1, 2\})\), the number of times \( C \) crosses the intersection curve, \( C \), must be equal to the number of times \( C \) crosses the rail curve, \( C_i^r \) (see Figure 2.8). The following lemma shows that if this condition is satisfied, \( n = m \) and we have a proper matching:

**Lemma 2.4.1.** Let \( L_1^u, L_1^v, L_2^u, L_2^v \) be the subdivision values obtained from Algorithm 4. If for each \( u \)-subdivision step, \( u_0 \in L_i^u \) \((i \in \{1, 2\})\), the iso-parametric curve, \( C_i(v) = S_i(u_0, v) \), intersects with the intersection curve, \( C(t) \), the same number of times it intersects with the rail curve, \( C_i^r(t) \) (i.e. \(|C_i(v) \cap C(t)| = |C_i(v) \cap C_i^r(t)|\), where \(|·|\)
denotes the cardinality of the set), and a similar condition holds for each \( v \)-subdivision step, \( v_0 \in L_i^v \), then after subdividing \( S_1 \) and \( S_2 \) along all of the subdivision values in \( L_1^u, L_1^v, L_2^u \) and \( L_2^v \), \( \hat{S}_1 \) and \( \hat{S}_2 \) will be split into the same number of sub-surfaces.

**Proof:** Let \( i \in \{1, 2\} \) and let \( j \) be the index corresponding to the other surface. Because each isoparametric curve we subdivide along, crosses both \( C(t) \) and \( C_i^r(t) \) the same number of times, the number of sub-surfaces of \( \hat{S}_i \) is uniquely determined by the number of intersection points between \( C(t) \) and the isoparametric curves we subdivide \( S_i \) along. Since for each subdivision isoparametric curve, \( C_i \) of \( S_i \), and for each intersection point, \( C(t_0) \in C_i \cap C \), Algorithm 4 matches a subdivision isoparametric curve, \( C_j \) of \( S_j \), that also crosses \( C \) at \( C(t_0) \), we deduce that the number of intersection points between \( C \) and the subdivision isoparametric curve of \( S_i \) is equal to the number of intersection points between \( C \) and the subdivision isoparametric curves of \( S_j \). Thus, the lemma holds.

Before introducing the fillet construction algorithm for B-spline geometry, we define the following data structure:

**Definition 2.4.2.** A FilletBoundary is a data structure holding the following fields:

- \( i \) - either 1 or 2. Specifies whether this boundary corresponds to a sub-surface region of \( S_1 \) or \( S_2 \)
- \( \hat{S} \) - a sub-surface region of \( S_i \)
- \( \tilde{c} \) - a sub-curve of the intersection curve, \( c_i^S \), in the parametric space of \( S_i \)
- \( \tilde{c}_r \) - a sub-curve of the rail curve, \( c_i^r \), in the parametric space of \( S_i \)

Further, we assume each instance, \( FB \), of the FilletBoundary data structure supports the following functionalities:

- \( FB.Split(C) \): Receives an iso-parametric curve, \( C \), of \( S_i \) as an input. If \( C \) is also an isoparametric curve of \( \hat{S} \), the function splits \( \hat{S} \) along \( C \), splits \( \tilde{c} \) and \( \tilde{c}_r \) on each of their intersection points with \( C \) and returns a list of FilletBoundaries, corresponding to the sub-surfaces and sub-curves resulting from splitting the original FilletBoundary. If \( C \) is not an isoparametric curve of \( \hat{S} \), the function does nothing and returns a list containing one item - the original FilletBoundary.

- \( FB.Verify(C) \): Receives an iso-parametric curve \( C \), of \( S_i \), returns true if the number of times \( C \) crosses \( \tilde{c}_r = S_i(\tilde{c}_r) \) is equal to the number of times \( C \) crosses \( \hat{C} = S_i(\tilde{c}) \), and returns false otherwise.
Algorithm 5 utilizes the above data structure to construct a list of trivariates, that together form the whole fillet between the B-spline primary surfaces, if possible. The algorithm splits the two primary surfaces into Bézier sub-surfaces and constructs a separate fillet between each pair of Bézier sub-surfaces that share the same sub-curve, $\tilde{C}$, of the intersection curve, $C$. Note that we assume the input primary surfaces, $S_i$, the intersection curve, $C$, and the rail curves, $C^r_i$ are all continuous. Hence, after calling $\mathcal{FB}.\text{Split}(C)$ (Line 16 of Algorithm 5) to split the input geometry, the resulting pairs of sub-curves and sub-surfaces will connect continuously on $C$. This also ensures that each two adjacent fillet trivariates constructed by Algorithm 5 will connect continuously. As mentioned above, the algorithm operates under the assumption that each iso-parametric curve corresponding to one of the subdivision values computed by Algorithm 4 crosses the intersection curve, $C$, the same number of times it crosses the rail curve, $C^r_i$, throughout the subdivision process. This condition is checked in Line 14. Again, recall Figure 2.6 for an example of a fillet construction between two B-spline surfaces.

### 2.4.3 Volumetric Filleting Construction by Surface Fitting

Recall that the filleting algorithms introduced so far depend on surface-surface composition to compute a tensor product representation of the fillet boundary surfaces, $\hat{S}_i \subset S_i$, under the assumption that the two composed surface regions are Bézier surfaces. In this section, we propose an alternative to the computation of a tensor product representation of (an approximation of) the required sub-surfaces. The (approximated) fillet construction method introduced in this section supports both Bézier and B-spline surfaces in general positions (i.e. possible crossing of knot lines).

Let $c_1, c_2 \in S_i$ be two curves in the domain of $S_i$, $i \in \{1, 2\}$, and recall

$$s_r(u, v) = Rld(c_1, c_2)(u, v) = (1 - v)c_1(u) + vc_2(u)$$

is a ruled surface between $c_1$ and $c_2$. To compute an approximation of the sub-surface $\hat{S}_i = S_i(s_r)$, we uniformly sample a set of points, $\{(u_j, v_j)\} \subset s_r$, in $S_i$’s domain, only to compute a B-spline surface that least-square-fits ([CRE01]) the set of their Euclidean images, $\{S_i(s_r(u_j, v_j))\}$. The control points of the boundaries of the resulting open-end B-spline surface can be fixed to ensure an accurate interpolation of the boundary curves, and with sampling that ensures the Schoenberg Whitney interpolation conditions [CRE01]. For example, the surface-surface composition in Line 3 of Algorithm 2 can be replaced by this least-square-fitting method to compute an approximation of $\hat{S}_i$, thus extending previous Algorithm 2 to also support B-spline surfaces in general position. See Figure 2.9 for examples of a fillet created following the above least-square-fitting method.
Algorithm 5: Fillet construction for B-spline primary surfaces.

Input:

$S_1(u_1, v_1), S_2(u_2, v_2)$ - the primary Bézier surfaces;
$c^S_i(t)$ - intersection curve in parametric space of $S_i$;
$c^r_i(t)$ - rail curve in the parametric space of $S_i$;
$C(t)$ - intersection curve in Euclidean space;

Output:

$L_f$ - a list of trivariates, forming the whole fillet;

$\text{BspTrivarFillets}(S_1, S_2, c^S_1, c^S_2, c^r_1, c^r_2, C)$:

1. $B_1 = (1, S_1, c^S_1, c^r_1)$,
2. $B_2 = (2, S_2, c^S_2, c^r_2)$; // Definition 2.4.2.
3. $L_1^u, L_1^w, L_2^u, L_2^w = \text{GetSubdivVals}(S_1, S_2, C)$; // Algorithm 4.
4. $L_{B1} = \{B1\}$; // A list containing $B1$
5. $L_{B2} = \{B2\}$; // A list containing $B2$
6. $L_f = \emptyset$;
7. // Subdivide at all values computed by Algorithm 4.
8. for $i \leftarrow 1$ to $2$ do
9.  foreach SubdivisionVal, $s \in L_i^u \cup L_i^w$ do
10.  $L(t)$ = iso-parametric curve on $S_i$ corresponding to $s$;
11.  foreach $B \in L_{Bi}$ do
12.      $L_{Bi}.pop(B)$;
13.      if !$B.\text{Verify}(L)$ then
14.          // Cannot fit a fillet!
15.              return $\emptyset$;
16.          $L_{Bi} = L_{Bi} \cup B.\text{Split}(L)$;
17.  foreach $B_1, B_2 \in L_{B1}, L_{B2}$ sharing the same sub curve, $C' = B_i.S'(B_i.c')$ do
18.      $L_f = L_f \cup B.\text{BzrFillet}(B_1.S', B_2.S', B_1.c'_r, B_2.c'_r, C', \tau)$; // E.g.
19.      Algorithm 2
20. return $L_f$.
Figure 2.9: In (a), two surfaces, $S_1(u, v)$ and $S_2(u, v)$ are shown, along with the sub-regions of $S_1$ and $S_2$ that are to be filleted, $\hat{S}_1$ and $\hat{S}_2$, between the intersection curve, $C(t)$, and the rail curves, $C'_i(t)$. (b) presents (an approximation of) the two subregions, $\hat{S}_1$ and $\hat{S}_2$, between the intersection curve, $C(t)$, and the rail curves, $C'_i(t)$, computed by the least-square fitting method described in Section 2.4.3. (c) is a zoom in view of $\hat{S}_1(u, v)$. (d) presents the computed fillet trivariate, $T(u, v, w)$, resulting from replacing Line 3 in Algorithm 2 by a least-square-fitting of $\hat{S}_i$. $\hat{S}_i$ were sampled at $(12 \times 105)$ locations in the domain, for the least-squares fit, and have $(7 \times 35)$, for $\hat{S}_1$, and $(3 \times 35)$, for $\hat{S}_2$, control points.
2.5 Volumetric Filleting using Trimmed Trivariates

In this section, we utilize the V-rep framework, introduced in [ME16], to construct a volumetric fillet. In the V-rep framework, a volumetric space can be represented as the sub-domain of one or more B-spline tensor product trivariates, that are delineated by trimming (and possibly trimmed) surfaces in Euclidean space.

To construct a V-rep fillet between $S_1$ and $S_2$, we initially compute a tensor product trivariate containing the filleted space, only to trim it by the fillet’s boundary surfaces, $\hat{S}_1$, $\hat{S}_2$ and $S_b$ (recall Algorithm 1) obtaining the desired V-rep fillet. The following operation, which we denote half Volumetric Boolean Sum, is introduced to compute a tensor product trivariate containing the fillet space. Following the notations of the previous sections, and as before let $\hat{S}_i(u, v) = S_i((1 - v)c^S_i(u) + vc^c_i(u))$, $i \in \{1, 2\}$, be the sub-regions on $S_i$ that serve as the boundary surfaces of the fillet, and let $C(u) = S_i(c^S_i(t)) = \hat{S}_i(u, 0)$ be the intersection curve of $S_1$ and $S_2$ in Euclidean space.

**Definition 2.5.1.** The half Volumetric Boolean Sum of $\hat{S}_1$ and $\hat{S}_2$, is the trivariate:

$$T_{hbs}(u, v, w) = \hat{S}_1(u, v) + \hat{S}_2(u, w) - C(u).$$

The name half Volumetric Boolean Sum stems from the fact that this constructor is a subset of the regular Volumetric Boolean Sum [EKK12]. Figures 2.10 (b) and 2.11 (b) show two examples of a half Boolean sum trivariate, $T_{hbs}(u, v, w)$. The half Volumetric Boolean sum operation can also be viewed as an extension of the Volumetric Boolean sum operation, for the case in which only two adjacent surfaces are employed.

**Lemma 2.5.2.** The boundaries of the half Volumetric Boolean sum, $T_{hbs}$, interpolate the two input surfaces:

$T_{hbs}(u, v, 0) = \hat{S}_1(u, v)$, and $T_{hbs}(u, 0, w) = \hat{S}_2(u, w)$.

**Proof:** We prove that $T_{hbs}(u, v, 0) = \hat{S}_1(u, v)$, while the other case can be similarly proven:

$$T_{hbs}(u, v, 0) = \hat{S}_1(u, v) + \hat{S}_2(u, 0) - C(u)$$

$$= \hat{S}_1(u, v) + C(u) - C(u)$$

$$= \hat{S}_1(u, v).$$

The trimming surfaces of the half Volumetric Boolean sum trivariate, $T_{hbs}$, that delineate the fillet zone are the boundary surfaces, $\hat{S}_1$ and $\hat{S}_2$, of $T_{hbs}$ as well as the
blending surface $S_b$. $S_b$ is computed by Algorithm 1, while $\hat{S}_1$ and $\hat{S}_2$ can be derived via either surface-surface composition or least-squares fitting.

If the intersection curve, $C(t)$, is closed, the fillet forms a loop and is closed as well, and $\hat{S}_1$, $\hat{S}_2$ and $S_b$ constitute the whole boundary of the fillet. However, if $C(t)$ is open, two additional capping, triangular like, surfaces, $S_{1,\text{cap}}$ and $S_{2,\text{cap}}$, are derived (see Figure 2.10), from the open boundary curves of surfaces $\hat{S}_1$, $\hat{S}_2$, and $S_b$. Algorithm 6 summarizes the above process of constructing a V-rep based fillet using a trimmed trivariate. Regardless of $C(t)$ being closed or open, the set of trimming surfaces, $L$, is forming a closed 2-manifold to properly trim $T_{hbs}$. Figures 2.10 and 2.11 show two examples of the output of Algorithm 6. In Figure 2.10, the intersection curve, $C(t)$, is open, and therefore two caps should be computed, while in Figure 2.11, the intersection curve, $C(t)$, is closed, and no caps are constructed.

**Algorithm 6:** Computing filleting trivariate by V-rep method.

**Input:**
- $\hat{S}_1(u, v)$, $\hat{S}_2(u, w)$ - fillet boundary sub-regions on $S_1$ and $S_2$;
- $S_b(u, v)$ - blending surface;
- $C(u)$ - intersection curve in Euclidean space;

**Output:**
- $V$, a V-rep model representing the fillet;

1. $\text{VrepFillet}(S_1, S_2, S_b, C)$:
2. $T_{hbs}(u, v, w) = \hat{S}_1(u, v) + \hat{S}_2(u, w) - C(u)$;
3. $L = \{\hat{S}_1, \hat{S}_2, S_b\}$;
4. if $C(t)$ is open then
5. $S^c_1 = T_{hbs}(0, v, w)$;
6. $S^c_2 = T_{hbs}(1, v, w)$;
7. for $i \leftarrow 1$ to 2 do
8. $C_1^{S_b}(t) = S^c_i \cap S_b$;
9. $C_1^{S_2}(t) = S^c_i(t, 0)$;
10. $C_1^{S_1}(t) = S^c_i(0, t)$;
11. $S_{1,\text{cap}}^c = \text{A trimming surface to } T_{hbs} \text{ from surface } S^c_i, \text{ using closed trimming loop } \{C_1^i, C_1^u, C_1^v\}$;
12. $L = L \cup \{S_{1,\text{cap}}^c, S_{2,\text{cap}}^c\}$
13. $V = \text{V-rep model resulting from trimming } T_{hbs} \text{ by set of surfaces } L$;

### 2.6 Trivariate Filleting over Multiple Surfaces, Possibly over $C^1$ Discontinuities

Consider the problem of constructing a fillet trivariate between two trivariates, $T_1(u, v, w)$ and $T_2(u, v, w)$, that have $C^1$ discontinuities along the filleting zone - along their intersection curve, $C$. See Figure 2.12. Let $S_{1,i}$ and $S_{2,i}$, $i \in \{0, \ldots, 5\}$, be the six boundary surfaces of tensor product trivariates $T_1$ and $T_2$, respectively. Let $\partial T_k = \bigcup_{i=0}^5 S_{k,i}$,
Figure 2.10: (a) A cylinder, $S_1$, intersects with a planar surface, $S_2$, along the intersection curve, $C$. $C_i$, $i \in \{1, 2\}$, are the rail curves on $S_i$, respectively, and the sub-surface regions, $\hat{S}_i = S_i(Rld(c^S, c^T_i))$, are the boundaries of the fillet on $S_1$. (b) presents the half Volumetric Boolean sum trivariate, $T_{hbs}$, between surfaces, $\hat{S}_1$ and $\hat{S}_2$ (see Definition 2.5.1). Herein, the intersection curve, $C$, is not closed, and hence in (c), two capping surfaces are constructed. $S^c_{Cap}$ is computed by trimming the boundary surface $S^c = T_{hbs}(0, v, w)$ by curves $C_{S_b} = S_b(0, v)$, $C_{1}^0$ and $C_{v}^1$. The final V-rep model fillet, created by Algorithm 6, is shown in (d), from a different viewing direction.

$k \in \{1, 2\}$, and $C = \partial T_1 \cap \partial T_2$, and for each $0 \leq i \leq j \leq 5$, denote $C_{i,j} = S_{1,i} \cap S_{2,j}$. That is, intersection curve $C = \bigcup_{0 \leq i \leq j \leq 5} C_{i,j}$. Hence, we now assume that $C(t)$ is closed but only piecewise-$C^1$. Further, let

$$\mathcal{C}[\cdot] = \{C_{0,0}, C_{1,1}, C_{2,2}, \ldots\}$$

be a vector containing the $M$ intersection curves, $C_{i,j}$, sorted in a clockwise order (looking from outside). The filleting process we introduce in this section consists of two main steps. Initially for each $0 \leq i \leq j \leq 5$ such that $C_{i,j} \neq \emptyset$, we construct a separate fillet trivariate between $S_{1,i}$ and $S_{2,j}$, using algorithms discussed in the previous sections. This set of fillets might not form a closed fillet object, due to $C^1$ discontinuities in the intersection curves. Therefore, in Section 2.6.1, a second, new, step of this filleting process is discussed, constructing additional fillets that bridge all gaps between the trivariates constructed in this first step.

One should note that the approach we describe in Section 2.6.1 is best fitted to handle convex $C^1$ discontinuities of the intersection curve, $C$. While convex $C^1$ discontinuities result with the existence of gaps between adjacent rail curves, concave $C^1$ discontinuities would result with the adjacent rail curves crossing each other. Such concave discontinuities could be similarly handled, as we describe here, while it would result with $C^1$ discontinuities on the fillet surface, along the trimmed location. In the rest of this section, we focus on creating smooth convex fillets, while we leave the
Figure 2.11: In (a), the spout, $S_1$, of the Utah teapot, is shown intersecting with the body, $S_2$, of the Utah teapot, along the intersection curve, $C$. $C_i^r$, $i \in \{1, 2\}$, are the two rail curves on $S_i$, and the sub-surfaces, $\hat{S}_i = S_i(Rld(c_i^S, c_i^r))$, are the boundaries of the fillet on $S_i$. In (b), the half Volumetric Boolean sum trivariate, $\mathcal{T}_hbs$, of $\hat{S}_1$ and $\hat{S}_2$ is presented (see Definition 2.5.1). (c) shows the V-rep model fillet created by Algorithm 6. See also Figure 3.4.
handling of concave \( C^1 \) discontinuities for future work.

### 2.6.1 Bridging the Gaps in the Fillets, near \( C^1 \) discontinuities

The two trivariates to be filleted, \( T_1 \) and \( T_2 \), might contain \( C^1 \) discontinuities along \( C \). Hence, after offsetting all \( M \) intersection curves, the resulting set of \( M \) rail curves,

\[
\{ R^{k}_{m, j} \}_{m=0}^{M-1}, \quad 0 \leq i \leq j \leq 5, \quad k \in \{1, 2\},
\]

might not form a \( C^0 \) closed continuous rail curve. That is, gaps will exist between adjacent rail curves in the set, again, due to \( C^1 \) discontinuities in the intersection curves (see Figures 2.12).

Let \( C_{im,jm} = C[m] \) and \( C_{im+1,jm+1} = C[m+1] \), be two adjacent intersection curves with a \( C^1 \) discontinuity. This discontinuity can happen due to \( T_1 \) being discontinuous, \( T_2 \) being discontinuous, or both. We assume that the event where both \( T_1 \) and \( T_2 \) are simultaneously discontinuous at the same location is not likely and ignore it. Hence, and without loss of generality, we assume that there is a gap between \( R^1_{im,jm} \) and \( R^1_{im+1,jm+1} \), while \( R^2_{im,jm} \) and \( R^2_{im+1,jm+1} \) are connected with a \( C^0 \) continuity (The other case is symmetric). Recall that all intersection curves form together a close, \( C^0 \) continuous, curve. Thus, \( C_{im,jm} \) and \( C_{im+1,jm+1} \) share an endpoint. Let \( o \) be the shared endpoint of \( C_{im,jm} \) and \( C_{im+1,jm+1} \), let \( p \) be the last point of \( R^1_{im,jm} \), and let \( q \) be the first point of \( R^1_{im+1,jm+1} \) (See Figure 2.12 (e)).

Because the rail curves are computed as Euclidean offsets of the intersection curves, it holds that \( d(C_{ij}, R^1_{im,jm}) = d(C_{im+1,jm+1}, R^1_{im+1,jm+1}) \), and hence, \( d(o, p) = d(o, q) = d \). Let \( B_d \) be the locus of points on \( S_{im} \) and \( S_{im+1} \) that have a Euclidean offset distance \( d \) from \( p \). The subset of \( B_d \) between \( p \) and \( q \) is used to bridge the rail curves, \( R^1_{im,jm} \) and \( R^1_{im+1,jm+1} \). Then, a trivariate fillet is constructed between \( o \) and the subset of \( B_d \) between \( p \) and \( q \), just computed, to fill the gap. Note this new trivariate fillet that bridges between the last face of the fillet of intersection curve \( C_{im,jm} \) and the first face of the fillet of intersection curve \( C_{im+1,jm+1} \) is singular along the \( C^0 \) discontinuity of input filleted trivariate, \( T_i \). Again, Figures 2.12 illustrate this computation process of adding these singular trivariate fillets.

### 2.7 Blending Materials and Properties

Applications of our filleting algorithms, such as 3D printing, require the encoding of heterogeneous properties into the constructed fillet, in a way it continuously connects with the two primary surfaces. Thus, we now consider the question of blending the given heterogeneous property functions of the two input surfaces, \( S_1 \) and \( S_2 \), restricted to the filleted area, \( \hat{S}_1 \) and \( \hat{S}_2 \). In other words, we seek to encode blended properties into the trivariates(s) of the fillet that were constructed in previous sections, so as to ensure that the property values are continuous in-between \( \hat{S}_1 \) and \( \hat{S}_2 \).
Figure 2.12: Filleting over $C^1$ discontinuities. (a) shows all the intersection curves, $C_{i,m,j,m}$, of the cylinder surfaces, $S_{1,i}$, and the surfaces of the box, $S_{2,j}$, as well as the corresponding rail curves. In (b), the Euclidean offset curves from (a) are clipped and stitched together, forming the rail curve(s). Filleting the corresponding pieces, gaps forms at $C^1$ discontinuities, as shown in (c). In (d), the intersection curves, $C_{2,2} = S_{1,2} \cap S_{2,2}$ and $C_{3,0} = S_{1,3} \cap S_{2,0}$, are offseted on the boundary surfaces of the cylinder, $S_{1,2}$ and $S_{1,3}$, forming two disjoint pieces of the rail curve on the cylinder, $R_{1,2}^1$ and $R_{3,0}^1$, that end at $p$ and $q$. A singular fillet is constructed between $p$ and $q$, around $o$, to bridge the gap. Finally, this singular fillet, along with other fillet trivariates form the whole fillet between the box and the cylinder, are shown in (e).
Let $\mathcal{T}$ be a fillet trivariate and let $\hat{S}_1 \subset S_1$ and $\hat{S}_2 \subset S_2$ be the two boundary surfaces of the fillet. We assume that each surface, $\hat{S}_i$, is associated with a unique property function, $g_i$, encoding properties of $\hat{S}_i$ (such as material). Each property function, $g_i$, is a multi-variate B-spline that shares the same parametric domain with $\hat{S}_i$. Without loss of generality, we assume $g_i$ to be a scalar function with sufficient continuity and we denote it as $g_i$. All the following discussion can be easily adapted to the general multivariate setting (vector, tensor etc.) by applying the same material encoding method to each coordinate.

Section 2.7.1, describes a method to directly encode the required property into the control points of the fillet trivariate, as a convex combination of the control points of $g_i$, hence exploiting parametric distances. A more precise blending scheme, based on Euclidean distances, which also employs the volumetric fillet representation described herein, is discussed in [MCE].

### 2.7.1 Direct (Parametric) Property Blending

Assume $\mathcal{T}$ is a fillet trivariate constructed as a ruled volume between the merged two primary surfaces, $\hat{S}_{12} = \hat{S}_1 \cup \hat{S}_2$ and the blending surface $S_b$ (recall Algorithm 2). Further, assume that $\hat{S}_{12}$ and $S_b$ are two surfaces that share the same function space. If not, one can always bring both surfaces into a common function space via degree raising and refinements.

Denote by $n_u, n_v$ the number of coefficients of $\hat{S}_{12}$ and $S_b$ and consider

$$g_i(u, v) = \sum_{m=0}^{n_u-1} \sum_{r=0}^{n_v-1} B_{m,r}^{(i)}(u,v) p_{m,r}^{(i)},$$

where $B_{m,r}^{(i)}$ are the basis functions of $g_i$. Bringing $g_i$, $i = 1, 2$, into a common function space, we will have $g_i(u, v) = \sum_{m=0}^{n_u-1} \sum_{r=0}^{n_v-1} B_{m,r}(u,v) p_{m,r}^{(i)}$. To continuously encode the blended properties into $\mathcal{T}$, we first associate $S_b$ with the following property function:

$$g_b(u, v) = \sum_{m=0}^{n_u-1} \sum_{r=0}^{n_v-1} (1 - \alpha_r) B_{m,r}(u,v) p_{m,r}^{(1)} + \alpha_r B_{m,r}(u,v) p_{m,r}^{(2)}$$

where $\alpha_r = \frac{r}{n_v - 1}$. Note that $g_b(u, v) = g_1(u, v)$ for $\alpha_r = 0$ and $g_b(u, v) = g_2(u, v)$ for $\alpha_r = 1$.

Then, a process similar to Algorithm 2 can be utilized to merge the two property functions, $g_1$ and $g_2$, as

$$g_{12}(u, v) = \begin{cases} g_1(u, 2v), & 0 \leq v \leq 0.5, \\ g_2(u, 2(v - 0.5)), & 0.5 < v \leq 1. \end{cases}$$ (2.9)
only to serve as the property function associated with the merged surface \( \hat{S}_{12} \) (recall Equation (2.5)).

Then, the property function, \( g_T(u, v, w) \), encodes the ruled trivariate fillet \( T \), as:

\[
g_T(u, v, w) = (1 - w)g_{12}(u, v) + wg_b(u, v),
\]

after bringing \( g_{12} \) and \( g_b \), once more, to a common function space.

One should note that if \( g_1 \) and \( g_2 \) have different property values along the intersection curve, \( C = \hat{S}_1 \cap \hat{S}_2 \), then \( g_{12} \) and hence \( g_T \) will be discontinuous there. Otherwise, this simple interpolatory scheme will yield \( C^0 \) continuity along \( \hat{S}_1 \) and \( \hat{S}_2 \).
Chapter 3

Results and Examples

We present several examples of heterogeneous fillets computed for and in-between different pairs of trivariates with heterogeneous properties, herein represented as rgb colors. These rgb colors can represent, for example, material densities, stiffness tensors or heat conductivity factors, etc. The computation, unless otherwise stated, was conducted on a Windows machine with Intel i7 core 2.6GHz, 64 bit and 16GBs RAM.

Figures 3.1 and 3.2 show fillets that were computed based on Algorithm 2 and rgb property encodement that were computed as described in Section 2.7.1, using the direct (parametric) blending of properties (Section 2.7.1). It took less than a minute to compute each of these fillets. Figures 3.3 and 3.4 present a 3D printed example. Numerous images are used to create the necessary data-set to 3D print such models using the VoxelPrint [Str20] technology of Stratasys. A heterogeneous Utah teapot, in Figures 3.3 (a) and 3.4 (a), is being filleted using the described algorithms, in Figures 3.3 (b) and 3.4 (b), and then the geometry and materials were simultaneously sliced over three thousand times to yield the necessary data that created the 3D printed model, in Figures 3.3 (c) and 3.4 (c). It took a few hours to compute all the slices while the 3D printing process itself consumed almost a day, on a Stratasys machine.

Table 3.1 summarizes the number of control points and orders for in the input geometry and the resulting fillets, in these displayed results. Note that some entries present the values of multiple trivariates and hence are shown as ranges.
Figure 3.1: A heterogeneous fillet computed between two tri-cubic spheres. In (a), the two spheres are shown, after heterogeneous data in $E_6$ has been independently encoded into them, as $(x, y, z, r, g, b)$. (b) shows the computed final fillet, following Algorithm 2, while the blending of the $rgb$ properties was computed as described in Section 2.7.1.
Figure 3.2: A heterogeneous fillet computed between a sphere and a cone. In (a), intersecting sphere and cone are shown, after heterogeneous data in $E_6$ has been independently encoded into both, as $(x, y, z, r, g, b)$. (b) shows the computed fillet, following Algorithm 2, while the blending of the $rgb$ properties was computed as described in Section 2.7.1.
Figure 3.3: A heterogeneous fillet computed for the Utah teapot, between the body and the handle. In (a), the regular teapot is shown, after heterogeneous data in $E_6$ has been encoded into, as $(x, y, z, r, g, b)$. (b) shows the computed fillet, following Algorithm 2 while the $rgb$ blending was computed as described in Section 2.7.1. In (c), a 3D printed model is shown, using a Stratasys 3D printer. See also Figure 3.4.
Figure 3.4: A heterogeneous fillet computed for the Utah teapot, between the body and the spout. In (a), the regular teapot is shown, after heterogeneous data in $E6$ has been encoded into, as $(x, y, z, r, g, b)$. (b) shows the computed fillet, following Algorithm 2 while the $rgb$ blending was computed as described in Section 2.7.1. In (c), a 3D printed model is shown, using a Stratasys 3D printer. See also Figure 3.4.

Chapter 4

Conclusion and Future Work

This work presented several methods for the construction of trivariate fillets, and discussed two possible methods to encode heterogeneous material into the computed fillet. The trivariate fillet construction algorithms introduced herein support varying sets of surfaces, and each algorithm works under different assumptions. While Section 2.4.3 presents a method to create an approximated fillet between two general intersecting B-spline surfaces, the problem of constructing a precise trivariate fillet for two B-spline surfaces in general position (crossing knot line) is still open, and is an area for future work.

While the approaches we introduced are shaped to approximately achieve symmetric or qualitative measures (e.g. improved Jacobian values and preserving continuity), these were not the main focus of this work. Methods for qualitatively formalizing and optimizing fillets should be investigated. This, with the understanding that by definition, at the rail curves, the Jacobian of all presented approaches vanish, simply because $S_b$ is tangent to $S_i$.

The computed fillets join the boundary surfaces of the filleted trivariates with geometrically $C^1$ continuity. Yet, the property functions adhere to only $C^0$ continuity over the $\hat{S}_i$. Higher geometric continuity can be achieved using known methods such as quintic Hermite (for $C^2$ geometric continuity). That said, future work should strive to extend the presented filleting and heterogeneity encodement methods to achieve higher order continuity of properties.

One should remember that if two different geometries present different properties at the intersection curve $C$, the geometry will present a discontinuity in the property. In fact, in all presented examples in this work, we intentionally encoded independently different property values in the different input trivariates (and their boundary surfaces). Such a difficulty better be managed before the fillet is applied, striving to ensure the properties are smooth or at least continuous along $C$, if possible.

The context of this work was limited to the filleting of two intersecting trivariates. Therefore, a possible continuation of this work may be extending the introduced filleting algorithms to support the filleting of more than two intersecting objects. Moreover,
while the two input trivariates were allowed to have $C^1$ discontinuities along their intersection curve, the proposed handling of concave $C^1$ discontinuities results with the rail curves being $C^1$ discontinuous. Other methods for the handling of concave discontinuities should be investigated. Further, while in Section 2.3.2, the capping surfaces of the fillet were generated by Boolean Sum, one should generally ensure the capping of adjacent fillet trivariates is done in a continuous manner. This capping construction process is yet another degree of freedom to explore and an area for future work.

All of the presented filleting Algorithms depend on the Hermite interpolation scheme to construct the blending surface, while, clearly, other surface blending schemes may be combined with the presented trivariate Algorithms. Additionally, the filleting methods we introduced strongly depended on surface-surface compositions, which makes the amount of the control points in the constructed fillet grow rapidly. Methods for minimizing the number of control points in the resulting fillet should be investigated as well.

Finally, and while we also showed that we are able to 3D print the synthesized geometry with independent encodement of properties, the analysis of such fillets pose a challenge. To begin with, the geometry of the constructed fillet is not compatible with the boundary surfaces, $S_i$, and hence mortar methods or similar might be required to 'glue' the geometries. Then, and while the Jacobian is positive in the interior of the fillet, the Jacobian of the fillet vanishes at the rail curves. The behavior of such fillets in analysis and in iso-geometric analysis in specific, is yet to be examined.
Appendix A

Computing the Division of the Fillet Space toward Volumetric Boolean Sum

Recall Figure 2.4 for this appendix. Let \( p = C(0.5) \) be the mid-point of the intersection curve, \( C(t) \). Orthogonally project \( p \) on the iso-parametric curve, \( C_{mid}^b(v) = S_b(0.5, v) \), by solving the following constraint for \( v \):

\[
\left\langle p - C_{mid}^b(v), \frac{dC_{mid}^b(v)}{dv} \right\rangle = 0.
\]  

(A.1)

Let \( p_b = C_{mid}^b(v_b) = S_b(0.5, v_b) \) be the point that satisfy the above constraints and whose Euclidean image on \( S_b \) is the point closest to \( P \). Define \( C_b \) to be the \( u \) iso-parametric curve of \( S_b(u, v) \) that passes through \( p_b = (0.5, v_b) \). I.e. \( C_b(u) = S_b(u, v_b) \).

To compute \( C_c(t) \), the centrally interior curve in the fillet space, we define

\[ S_r(u, v) = Rld(C, C_b) = (1 - v)C + vC_b, \]

to be the ruled surface between the intersection curve, \( C \), and the curve \( C_b \), just computed. Then,

\[
C_c(t) = S_r \left( t, \frac{\sqrt{2}}{1 + \sqrt{2}} \right) = C(t) + \frac{\sqrt{2}}{1 + \sqrt{2}} (C_b(t) - C(t)),
\]

(A.2)

divides the ruled surface, \( S_r(u, v) \), by ratio \( \sqrt{2} : 1 \). This ratio strives for a 'fair' division of the fillet space so that in the case where \( \hat{S}_1 \) and \( \hat{S}_2 \) are orthogonal (and \( S_b \) is forming a slope of \( \pi/4 \) at \( p_b \)), then the point \( C_c(0.5) \) will be equidistant from the three surfaces, \( S_b, \hat{S}_1 \) and \( \hat{S}_2 \) (See Figure 2.4(b)).

To compute the foot curves, \( C_i \), on \( \hat{S}_i(u, v) \), we follow a similar process. Let \( p_i = \hat{S}_i(0.5, v_i), i \in \{1, 2\} \), be the orthogonal projections of \( C_c(0.5) \) on the iso parametric
curve, \( C^i_{\text{mid}}(v) = \hat{S}_i(0.5, v) \) (computed as in Equation (A.1)). Then, foot curve \( C_i(u) \) is defined as the \( v \) iso-parametric curve on \( \hat{S}_i \) passing through \( p_i \). I.e. \( C_i(u) = \hat{S}_i(u, v_i) \).

Again, Figure 2.4(b) illustrates this computation process of building \( C_b, C_c, C_1 \) and \( C_2 \).

Algorithm 7 summarizes this division process as described in this appendix.

תקציר

The creation of a blending surface that connects the two spaces (blending) is the meaning of the problem. Given two objects, the language connects the objects in a partial way. In this work, we will extend the modeling surface to the three-dimensional surface. In other words, the goal is to create a solid body that fills the space between the two objects.

As we noted, the parts of the solid body fill the corner points on the surface and are connected in a partial way. The solid body is used for modeling, and it is significant for the field of design and modeling.

The problem of modeling surfaces that are surrounded by solid bodies is examined in a large area over the past decades, but in many cases, the surface is divided into parts. The issue of creating surfaces that are surrounded by solid bodies is considered.

In this work, we aim to create a blending surface that connects the two solid bodies and is connected in a partial way, both geometrically and in terms of the additional properties.

The formal definition

(i ∈ {1, 2})  

The language of the problem is that the solid bodies are connected, normally, the language is connected. Furthermore, the Jacobian of the basic solids is not zero at any point.

The algorithms that are presented in this work depend on the functionality and the geometric data that are present. The formula S₂ - S₁, S₁ is the blending surface, and S₂ is the initial surface. The formulas are given in the work. The algorithms are presented in the work. The algorithms are presented in the work. The algorithms are presented in the work.
The work was carried out under the supervision of Professor Gershon Elber, a faculty member of the Computer Science Department, and the results were published in articles written by the author and presented in seminars and journals during the period of his research.

Thank you to Professor Gershon Elber for his continuous support and for providing a valuable environment for the research period. I have learned from you the philosophy of work and its characteristics. I am grateful for your readiness to provide any type of assistance, from small problems to major obstacles, enabling me to develop the links to my research, to derive knowledge from my research and benefit from it.

I also thank my colleague Emiliano Cirillo, who invested enormous efforts to do his part of the work, and is under additional obligations and difficult circumstances. Your contribution is appreciated.

Finally, I thank my parents, Haldur Masalha and M. Elber, for their continued support and encouragement throughout. You have been with me every step of the way, and I hope you will continue to be with me.

The Technion's Computer Science Department provided financial support and encouragement during this period.

A note. The notes on the back are as follows:

A note for the notes on this page, if at all possible, to make the notes readable and clear.
